nt Symptoms

1. Objectives of the Work Proposed

The purpose of the proposed studies is to test certain aspects of personnity theory by comparing the subtest performance on the Westessenittelligence Scales of patient groups differing primerily in overt symptoms. The such studies are anticipated. The first will be an investigation of the Wechsler scores of a sample of conversion hysterics, and will include comparisons of comparable subgroups characterized by different symptoms. The second will consist of a comparison of the subtest performance of comparable groups of migraine and ulcer patients. It is proposed that the three major measurable type of the property of the subtest performance of comparable groups of migraine and ulcer patients. It is proposed that the three major measurable type of the property of the proper

For purposes of research advantages:

personality theory offers two major

- Some aspects of the theory are immediately and objectively verifiable.
- From a long-range point of view, the method by which the theory orders the data permits of relatively specific predictions concerning the individual's behavior.

In order to clarify some of the major theoretical considerations to be investigated, a brief summary of the theoretical considerations. The summary is
based on direct information from
and on Saunder's research meaoranda, (see bibliography). The received revenue of the more explicit statement in
a separate memorandum by Saunders (1).

According to the theory, the personality structure and function of the individual can be expressed in terms of three basic personality dimensions. These dimensions consist of the Externalizer-Internalizer, the Plexible-Rigid, and the Acceptable-Unacceptable continua. These will hereafter be referred to as the E-I, F-R, and A-U dimensions, respectively.

As the individual develops he is confronted with the task of reconciling his basic personality pattern with various environmental and social demands, which require him to modify his position on each of the three basic continue. His modifications represent the extent to which the individual is able to compensate for the limitations on adjustment imposed by his basic personality structure,

The theory further costulates that the individual's modifications of his besic personality pattern, as well as the basic dienesions themselves, are reflected by his performance on various subtests of the Mechaler Scales. Thus, his score on the Digit Span subtests shows his position with regard to the B-I dimension, his ultimate location on this continuum being determined by modifying factors which are indicated by his Arithmetic and Information scores. His Block Design score determines his placement on the F-R continuum, wouldfied by his performance on the Similarities and Comprehension subtests. His position on the A-U continuum is shown by his score on the Picture Arrangement subtest, modified by his Picture Completion and Object Assembly performance.

has developed a method of expressing the dynamic structure of the brinkidual, in terms of three formulae which are based on Wechsler subtest performance. These formulae, taken togother, represent the development of the individual's personality structure across time.

2. Wethod

Since the studies will test different hypotheses, certain procedures for collecting and treating the data will be different for the two investigations. Procedures which will be specific to each study are described first.

Those which will be common to both studies are discussed later, under the section devoted to the treatment of the data.

A. The Conversion Hysteric Study

Conversion hysteriae are thought to constitute an excellent group for an investigation of the protocolity theory, in that their particular symptoms presum representatives sential espects of the individual's dynamic structure.

A pilot study, based on 46 conversion subjects, has already been completed, and has provided results which are consistent with theoretical formulations. Though the number of subjects was functive call, perticularly in the comparisons based on subgroups, the obtained statistically significant findings and a number of trends which were found, are thought to be well worth a more extensive analysis with a larger sample. The pilot study is summerized in the Appendix of this proposal. Its results suggest the following hypotheses:

- Pronounced sensory and motor symptoms will be more characteristic of predominantly "E" individuals.
- Severe and frequently generalized headaches will occur more often in predominantly "l" subjects. (This does not include migraines, which theoretically constitute a different type of symptom).
- Predominantly "I" individuals will complain of fewer and less specific symptoms than will the predominantly "E" groups.
- 4. Both the F-R and the A-U continua will be related to symptom choice.
- Predominantly "I" and predominantly "E" subjects with low scores on the Picture Completion subtest of the Wechaler Scales will differ in their expressed symptoms, in accordance with theoretical expectations of their respective tendencies toward withdrawal and identification.
- 6. Behavioral differences apart from symptoms will characterize the predominantly "E" and the predominantly "I" groups, these differences depending to some extent on the location of the individual on the "PR and A-I continue."

Sample

The sample will consist of approximately 100 subjects, whose medical records do not indicate neurological pathology, and who have been diagnosed as conversion hysterics by examining neurologists. It is anticipated that the age range will not go below 15 or above 49 years, and that montally retarded subjects will be excluded.

Specific Procedures

- 1. The occurrence of the various first for the group as a whole?
- We chaler subtest performance of comparable subgroups characterized by different symptoms will be compared.
- Specific hypotheses pertaining to the relationships between symptom choice, personality structure, and behavior, as defined by the theory, will be tested.

4. The influence on Wechsler subtest performance of population variables such as age, sax, educational and socio-economic background, and intelligence (as measured by the individual's normal level, in accordance with the theory) will be analyzed.

B. The Comparisons of Ulcer and Migraine Patients

Ulcer and migraine patients have been selected bacaway their use permits the testing of a number of hypotheses which there here implies. These hypotheses are as follows;

- Theoretically, the predominantly "I" individual looper and is ideationally dominant, and tends toward withdrawal gas predicted that such subjects will be more characteristic to the ulcer groups.
- In contrast, the predominantly "E" individual looks outward, is
 perceptually dominant, and environmentelly sensitive. It is predicted by dominant, and environmentelly sensitive, it is predicted by the commental of the disprine patients will consist of
 subjects precommently in the "E" category.
- It is further enticipated that the strength of the "I" or "E" component of the individual's personality, as determined by the three formulae, will be a significantly differentiating factor.
- 4. With respect to the F-R continuom, it is predicted that ulcer patients will be pradominantly "P" individuals. The "F compensated" subjects in particular should tend toward ulcers, because of the continual physiological and psychological stress with which their equilibrium is maintained. Theoretically, 'low Block Design scores plus low Similarities performance should be more typical of ulcer sufferers, since a low Similarities score indicates a tendency toward repression. On the other hand, a high Similarities score in a low Block Design record points to greater control of emotionality and therefore to less need for repression, which would represent a contra-indication of the formation of ulcers.
- 5. It is hypothesized that the migraine patients will consist chiefly of predominantly "R" subjects. Compensatory factors, corresponding to those stated above in connection with predominately "P" groups, will be studied for the predominantly "R" subjects.
- 6. It is further hypothesized that the strength of the "P" or "R" components of the individual's personality structure, as represented by the three formulae, will be a significantly differentiation (actor.
- It is also anticipated that the quality of the individual's social relationships will be related to his psychological equilibrium, and possibly to his symptom choice as well. Therefore, his development along the A-D continuum will also be studied.

Sample

Approximately 50 ulcer and 50 migraine patients are anticipated. Insorers as possible, the groups will be limited to those without avidence of further medical complications. The diagnoses will be medically determined. Groups comparable with respect to age, sex, educational and socio-economic levels; and intelligence (as measured by normal-levels) will be used. It is anticipated that subjects will be restricted to those between the ages of 15 and 49, and will not include the mentally retarded.

Specific Procedures

- 1. The occurrence of the various formulae will be studied within each of the groups.
- The occurrence of the various will be compared.
- Specific hypotheses related to the symptoms of ulcers and migraines in terms of the theory will be tested.

Treatment of the Data

The experimental data will consist of the three formulas, computed for each subject, and based on weighted scores from the Wechsler subtests. Further, scores will be derived from a theory-determined weighting of verious degrees of compensation of the individual's basic tendencies, to produce three single scores for each subject on each continuom. These will be interpreted as representing the strength of the basic dimensions within the individual's personality configuration.

The data will be treated in accordance with theoretical predictions. Contingency tests, (Chi-square and Fisher's exact tests), will be applied, to determine the differential incidence of the various personality configurations within and between the groups.

In analyzing the results for the strength of the basic tendencies, tests of the differences in location of these score distributions within and between groups will be performed by means of the t distribution, or its non-parametric analogue, depending on the nature of the data obtained. The influence of pertinent population variables on test performance will probably be analyzed by appropriate analysis of variance techniques.

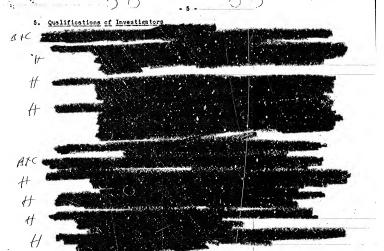

Although the studies will be undertaken to test a theory, (for which oneteiled tests of significance are sometimes used), only two-tailed tests will be employed, in order to permit the interpretation of contratheoretical results.

3. Period of time

A one-year project is anticipated.

Appendix

A Pilot Study in
Personality Theory

--0--

Sample

The sample control of white the medically examined and asychologically evaluated at the subjects are displayed as conversion hystorics of second and their records lacked indications of naurological pathology. The group ranged in age from 15 to 14, white a ween of 34.41. Normal levels ranged from 5 to 14, mean 10.44. There were 14 males and 32 females. They were tested on the Mechaler Bellevue Intelligence Scale, Form I.

Method

The experimental data consisted of the three requirements of the author of the subject on the basis of his weighted scores on the whohler subtests. The data were studied both for the group as a whole, and in comparisons of subgroups within it. Since different procedures were followed in the two types of analyses, and different results were obtained, they are separately presented below.

- I. The Pilot Study with the Whole Group, (N = 46).
 - A. Procedures

In the attempt to study symptom-choice, the following groupings were used for the various symptoms which the subjects manifested:

- Fainting spells, dizziness, drowsiness, and generalized states of weakness, shaking, and neusea.
 - . Pain in areas other than the head region.
- 3. Headaches.
- 4. Paralysis of extremities, and spasms, jerks, and numbers in those areas.
- 5. Pronounced sensory symptoms.
- 6. Numbness and jerking movements in the head and face region.
- B. Treatment of the Data and Results
 - Pronounced sensory symptoms (#5) were found in 7 of the 46 subjects and were significantly more characteristic of predominantly E individuals (as determined by the first formula). Age and normal

One-tailed tests of significance were used when direction was predicted in advance. Otherwise, two-tailed tests were used. Reported "trends" fell within the .10 to .20 levels.

² P < .02 by Fisher's exact test.

level³ did not significantly influence the occurrence of these symptoms, nor were any significant differences obtained between the compensated and uncompensated groups. However, a trand in the direction of increased numbers of subjects in the compensated groups, fig and EQ byes observed.

2. In studying the formulae of subjects with pronounced sensory symptoms, it was noted that the 3 cases in the group who surfered from hysterical blindness were P-uncompensated-compensated dividuals in their location on the F-R continuum. This suggested in their study of such subjects, of whom there were 9. These 9 ere almost equally divided between "I" and "B" subjects according to their first formulae, 7 becoming "B" individuals according to the second, All of them concluded as "I" individuals in the third formula, departing significantly from the hypothesis of an equal B-I split.

The above-mentioned results are thought to be in line with theoretical formulations in the following respects. Disturbances in the sensory areas would be more typical of "B" subjects, who are theoretically perceptually dominant and who, if maladjusted, would tend toward defensiveness in this respect.

Purther, in connection with a continuous, it would be shrustpated that subjects in whom the "" component was comperatively recent (i.e., appearing in the third formula only) would regain affected by their "F" characteristics, and be therefore subject to confusional states.

3. Numbness and jerking movements in the head and face regions (#6) ere significantly more prevalent among the "E" subjects! The jerking movements were especially common in these individuals. Since the latter were primarily motor disturbances, all of the subjects who suffered from motor disturbances, all of the subjects who trend in the direction of increased numbers in the "E" indivi.els was observed.

These findings, too, are thought to be consistent with the theory, in that motor disturbances would be expected in "B" groups, who are both perceptually dominant and environmentally sensitive.

4. Fainting spells, dizziness, drowsiness, and generalized states of weakness, shaking, and nausea (#1), which occurred in 15 of the 46 subjects, were significantly more characteristic of the dull group than of the brighter subjects. A trend was also found in the

³ For analyses based on age, the group was split at the median (37.69), creating a young and old group each with 23 subjects. Nonsignificant differences in their mean normal levels and sex distributions were obtained. In studying the influence of normal level, a bright group of 31 subjects with normal levels of 10 and over, and a dull group of 15 individuals with normal levels below 10 were used. No significant differences were found between their mean ages and their sex distributions.

⁴ pc .004 by the binomial test.

⁵ pc .015 by Fisher's exact test.

⁶ pc .008 by Fisher's exact test.

direction of more subjects in the uncompensated versus the compensated groups, with the greatest number of individuals falling in the uncompensated E category. Age was a nonsignificent factor.

These results are supportive of the theory, in that a less differentiated level of perceptual disturbance, reflected in sensory symptoms; would be anticipated in predominantly "E" subjects who are characterized by a lower level of intellectual functioning.

5. The following trends were also noted.

to the group into four quadrants according to roupings, subjects were distributed as follows:

Uncompensated I

Uncompansated

Compensated I

Compensated E

It can be seen that there is a trend toward the greatest numbers of subjects falling in the two compensated groups. While more subjects are needed for a more definitive breakdown in terms of quadrant placements, the predominance of compensated subjects is consistent with theoretical expectations.

b. A trend toward fewer symptoms, usually somewhat generalized in their nature, was found to be more characteristic of the "I" group, the "E" subjects having a greater number of relatively specific complaints. While the two compensated groups showed no marked difference in these respects, all of the 10 uncompensated I subjects complainted of 2 or less symptoms, while only 4 of the 8 uncompensated "R" individuals did so, the remainder complainting of 5 or more, Neither age nor normal level influenced those results to any marked extent.

The increased number of reported symptoms in the "E" subjects, as well as their relatively greater specificity, may again reflect their perceptual dominance and associated specificity, as compared to the ideationally dominant, more abstract "I" group.

 No significant results or marked trends were obtained with regard to the remaining symptom groupings. However, a more theory-oriented classification of these symptoms is thought to be worth attempting.

II. The Pilot Study with Subgroups. (N = 14),

A. Procedures

A subgroup was selected out of the whole sample, consisting of all subjects with low scores on the Picture Completion subtest of the Wecheler
Scale. A low FC score was defined as -3 or more in relation to the in
dividual's normal level. Fourteen of the 46 subjects met this criterion.
This subgroup was chosen because of the theoretical distinction made in
the meaning of a low FC score in a predominantly "I" and a predominantly
"B" individual. Theoretically, such a score in the former suggests with
caval in the direction of autism. On the other hand, in the latter, it
indicates withdrawal chiefly through identification. It was therefore
thought that this distinction might be reflected in symptom choice.

B. Treatment of the Data and Results

Seven of the 14 "low PC" subjects were found to be in the "I" category and 7 in the "E" group, as determined by the first formula. Six in each group were compensated, and I was uncompensated. The groups were closely matched in terms of sex distribution, ohronological age, and normal level, as well as on werbal, performance, and full-scale IQ, and renge and mean PC scores. 7

The following results were obtained:

 None of the 7 "B" subjects suffered from headaches, and all of the 7 "I" subjects suffered from severe headaches. (Note: None of these were migraines, the latter being absent in the conversion group. This is in line with theoretical expectations, since migraines constitute different symptom in terms of the individual's dynamic structure).

It is thought that these results are strongly supportive of the restrict lears, in that headaches would be more apt to occur in the ideationally-desirant I individuals. Further in most cases the "I" subjects reported headaches of a more or less generalized nature, suggesting the characteristic lack of specificity in such individuals.

2, Of the headsche sufferers, 3 reported no additional symptoms.
These were "iru" individuals according to the third formula,
and were also Isi across the three formulae. The remaining
"Ir subjects included 2 "iru"individuals; 1 "eru," and 1
"ifu." Thus, all of them concluded as "unacceptable" on
the A-U continuum, while 6 were originally "acceptable."

It may well be that the efforts at adjustment made by these subjects was further complicated by their unacceptability, which would theoretically reflect increased difficulties in the individual's social relationships, thus increasing the need for compensation.

3. In view of the apparent distinction in connection with headaches, the remainder of the conversion subjects (not characterized by low PC scores) was surveyed for the occurrence of this symptom. Nine such subjects were found, 4 in the "I" group and 5 in the "E", a clearly nonsignificant

⁷ Each group included 6 females and 1 male. The age range for the I group was from 17 to 44 years, mean 33.65, while that of the E group was 20 to 49, mean 33.15. No significant differences were found between the age ranges. Normal levels for the I subjects ranged from 8 to 12, mean 10.14, and for the F group from 9 to 13, mean 10.83, with nonsignificant differences obtained between them Nonsignificant differences were also obtained between their full-scale, verbal, and performance 19s. In both, PO-Scores were -3 to -7, means -5.00 & +3.63 (NS)

⁸ p by Fisher's exact test.

p < .016 by the binomial test.

This finding tends to support the rationals for conducting further study of "low PC" individuals with additional subjects, rather than considering the division in terms of "I" and "E" components alone.

4. In the "E" group, a trend toward symptoms centering primarily in the area of the legs and feet was noted. This was observed in 6 of the 7 "E" subjects, as opposed to 2 of the 7 "I" in-dividuals. There was also a predominance of walking difficulties among the "E" subjects.

Since 6 of the 7 in the "E" category were compensated, it may be that their motor difficulties reflect the later development of an "I" component, mitigating against a primarily environmentally dominated orientation.

On the A-U continuum, in contrast to the "I group, all of the "E" subjects began as "acceptable" according to the first formula, "O shifted to the "unacceptable", according to the second. 11 and were about equally divided in this respect on the third.

These findings suggest that the A-U continuum may be relevant to symptom-choice, perhaps operating differentially with basically different types of personality configurations.

 On the F-R continuum, both groups were approximately equally divided between "F" and "R" components according to the first and second formulae. However, according to the third, 6 of the 7-"I" subjects concluded as "R" individuals, while the "E" group remained about evenly divided between "R" and "F."

This trend toward increased rigidity on the part of "I" subjects with low PC scores would have considerable theoretical importance, if substantiated by further investigation. It also constitutes a further indication that the three basic continue and their interrelationships must all be taken into consideration in evaluating personality functioning, a point of view which the theory stresses.

- 7. When the subgroups were combined into a single "low PC" group. (N = 14), a significantly greater number of "compensated" as apposed to "uncompensated" subjects were gound (when compens to the possibility of an equal division). The relevance of this finding to the theory has already been commented on under results obtained for the whole sample.
- 8. Significant behavioral differences apart from symptoms were also obtained in comparing the two "low PC" groups. Among the "I" subjects, 5 of the 7 were characterized by periods of abrupt disruption of control with outbreaks of irrational emotional display, while none of the "E" subjects demonstrated this behavior. 13

Those results, which were based on the psychological and psychiatric records of the subjects, strongly suggest that further investigation with a larger sample might serve to support the theory in terms of differential emotic al reactions. It would be anticipated that the interrelations among the continua would be highly pertinent in this connection.

p < .016 by the binomial test.

p = .016 by the binomial test.

p < .01 by the binomial test.

Dec .025 by Fisher's exact test.

Summary of the Pilot Study

Some statistically significant results as well as a number of trends, in accord with theoretical appectations, were found in a pilot study based on 46 conversion subjects Tibe findings were related to the three major personality dimensions of the heavy, (i.e., the L.E. F.R., and A-U continue). Significant differences after twaiter, as well as in symptom-choice, were also noted. The conversion group appears to be well suited to a more extensive investigation of the theory, since symptom-choice presumably reflects besic aspects of the individual's dynamic structure. The preliminary work has suggested a number of hypothesses which warrant further testing with a larger sample. hypotheses which warrant further testing with a larger sample.
